LIST OF FIGURES

Chapter 1

Overview

Aber Fitness is a web application developed using Microsoft's *.NET Core* and Oracle's *Java Enterprise Edition* (henceforth referred to as Java EE). The project aims to provide a service to encourage fitness and promote engagement with sporting activities amongst the users of the application, offering functionality such as graphing fitness data gathered by owners of *Fitbit* devices, the ability to challenge other users to competitions and a sport ladder system with tight integration into a bespoke facility booking system. *Aber Fitness* aims to offer everything that would be needed by a sporty and active person in order to bring their sporting activities into a digital platform and also to enhance their use of devices they already own, such as *Fitbit* devices or smart watches such as the *Apple Watch*.

At launch the system will ingest activity data automatically from *Fitbit*, with the capability of easily implementing other health data provider services at a later date due to the modular nature of the data ingest system. Once normalised this activity data will be used throughout the various subsystems of *Aber Fitness*, providing users with functionality such as a dashboard overview of their activity over the last hour, day, week, etc. as well as integrating tightly into the challenges system to add a competitive aspect to the system in to keep users engaged with both the platform itself and keeping fit in general.

TODO: Possibly add more here? GDPR, Docker, Microservices, Auditing

Chapter 2

Design

2.1 System Overview

The *Aber Fitness* system is broken down into a number of microservices in order to aid portability, scalability and promotes a more maintainable codebase. After reviewing the initial project specification, the following microservices were created:

- **Booking & Facilities** - The *Aber Fitness* offers functionality for users to be able to schedule bookings at sports venues, such as swimming pools and squash courts. This microservice is called used by the *Ladders* service to create bookings for competitions.
- **Challenges** - The system offers the ability to give users activity challenges, for example completing a number of steps in a specific timeframe. These challenges can also be 'group' challenges, where a number of users can compete against each another to achieve goals such as furthest distance walked in a week, etc.
- **Communications** - This microservice provides an API for other services to send email notifications to users. It does not present any form of web UI, and users do not directly interact with it. This system could also be easily expanded to send out text messages, push alerts, etc. depending on future requirements.
- **Fitbit Ingest Service** - At launch, the *Aber Fitness* platform allows a user to link their *Fitbit* accounts to the system in order to import their activity data. The service periodically polls the Fitbit API for new data on the users' behalf, then stores this into the *Health Data Repository*.

With the possibility of adding future platform support the "ingest service" concept was created. This would allow us to support services such as Apple's *HealthKit* and other fitness tech providers. This architectural design means that activity data can be normalised by a number of "ingest services" before being passed through to the *Health Data Repository* service for storage.

- **Gatekeeper** - *Gatekeeper* is *Aber Fitness*'s OpenID Provider, and handles all authentication within the system. User credentials and account metadata is stored within *Gatekeeper*. *Gatekeeper* uses the OAuth 2.0 flow and is responsible for providing a single sign-on service for all of the various microservices. Microservices also contact *Gatekeeper* to obtain and verify tokens when calling internal APIs.
- **GLaDOS** - *GLaDOS* is the centralised auditing mechanism for *Aber Fitness*. It presents a REST API which is used to store audit data; such as when a user's data was accessed, modified, or deleted. *GLaDOS* provides a Status page which displays the availability of all the other microservices.

- **Health Dashboard** - *Health Dashboard* is the first interface users will encounter after logging in, or navigating to *Aber Fitness*. It provides the user with an overview of their recent activity as well as providing updates on any challenges or ladder competitions the user may be involved in.
- **Health Data Repository** - The *Health Data Repository* service is responsible for providing an API for accessing and storing activity data. It receives normalised activity data from the Ingest Services, and provides multiple API endpoints for other microservices to access user activity data.
- **Ladders** - *Ladders* is responsible for organising and managing ladder style competitions among users of the system. Users can compete in sporting championships for a variety of competitive sports such as tennis, running or cycling etc. The *Ladders* also automatically books venues for upcoming competitive events, which is managed by the *Booking Facilities* microservice.
- **User Groups** - *Challenges* can also be turned into a competition amongst users of a group. For example, a group may consist of a few friends or an entire office department. Users within a group compete to complete goals, such as who can achieve the most steps in a single day. The *User Groups* service is responsible for managing users into groups, and allowing users to leave and join other groups.
